## 0 - Ring Note

hat discovered about using an O-Ring ( $1 / 16$ thick) for a piston was gathered from conversations

 with modelers who use them and actual measurements from several engines. What I discovered was that there seemed to be consistancy on the amount of "compression" that the 0 -Ring should have. Compression is defined as the total difference between the diameter of the 0 -Ring Groove and the cylinder
ID. The number is between .004 and .005 .

|  | Cylinder <br> Bore | O-Ring Piston <br> Groove OD | Difference <br>  | O-Ring <br> Thickness <br> (2 $\times$ O-Ring Dia.) | Total <br> Compression |  |  |
| :--- | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| Engine 1 | .8665 | .731 | .1355 | .140 | .0045 |  |  |
| Engine 2 | .8752 | .740 | .1352 | .140 | .0048 |  |  |
| My Engine |  | 7393 | .135 | .140 | .005 |  |  |
| Target | .8743 | .739 | .1353 | .140 | .0047 |  |  |
| Actual | .8743 | .739 |  |  |  |  |  |
|  |  |  |  | Procedure to the fit the Piston |  |  |  |

First, I bored the cylinder, then honed it. Now I have the Bore Diameter
Second, I turned up the Piston to about . $0005-.001$ less than the bore.
Third, I calculate the Groove OD:
0 -Ring Cross Section Diameter $\mathbf{x} 2$ minus. 005 . I then subtract the value from the Bore Diameter which provides the Groove OD.

Forth, I finish up all the other operations to finish the piston.
Last, I lap the piston until it stays at the top due to air compression and when you lift it off the table it just drops through the cylinder.

## Measurements from three engines:

0 -Ring Cross Section Diameter $\times 2$ minus .005 . I then subtract th
$2 \times 3-48$ UNC $\downarrow .200$
Tap Drill \#47
